

How to: Configure a Windows Communication Foundation Service to Use Port Sharing

The easiest way to use `net.tcp://` port sharing in your Windows Communication Foundation (WCF) application is to expose a service using the [NetTcpBinding](#).

This binding provides a [PortSharingEnabled](#) property that controls whether `net.tcp://` port sharing is enabled for the service being configured with this binding.

The following procedure shows how to use the [NetTcpBinding](#) class to open an endpoint at the Uniform Resource Identifier (URI) `net.tcp://localhost/MyService`, first in code and then by using configuration elements.

To enable `net.tcp://` port sharing on a `NetTcpBinding` in code

1. Create a service to implement a contract called **IMyService** and call it **MyService**, .

C#

```
[ServiceContract]
interface IMyService
{
    //Define the contract operations.
}

class MyService : IMyService
{
    //Implement the IMyService operations.
}
```

2. Create an instance of the [NetTcpBinding](#) class and set the [PortSharingEnabled](#) property to **true**.

C#

```
NetTcpBinding portsharingBinding = new NetTcpBinding();
portsharingBinding.PortSharingEnabled = true;
```

3. Create a [ServiceHost](#) and add the service endpoint to it for **MyService** that uses the port sharing-enabled [NetTcpBinding](#) and that listens at the endpoint address URI `"net.tcp://localhost/MyService"`.

C#

```
ServiceHost host = new ServiceHost( typeof( MyService ) );  
host.AddServiceEndpoint( typeof( IMyService ),  
portsharingBinding, "net.tcp://localhost/MyService" );
```

Note

This example uses the default TCP port of 808 because the endpoint address URI does not specify a different port number. Because port sharing is explicitly enabled on the transport binding, this service can share port 808 with other services in other processes. If port sharing were not allowed and another application were already using port 808, this service would throw an [AddressAlreadyInUseException](#) when it was opened.

To enable net.tcp:// port sharing on a NetTcpBinding in configuration

1. The following example shows how to enable port sharing and add the service endpoint using configuration elements.

```
<system.serviceModel>  
  <bindings>  
    <netTcpBinding name="portSharingBinding"  
      portSharingEnabled="true" />  
  </bindings>  
  <services>  
    <service name="MyService">  
      <endpoint address="net.tcp://localhost/MyService"  
        binding="netTcpBinding"  
        contract="IMyService"  
        bindingConfiguration="portSharingBinding" />  
    </service>  
  </services>  
</system.serviceModel>
```
